

TPS6123x 具有 5A 开关的高效同步升压转换器

1 特性

- 输入电压范围：2.3V 至 5.5V
- 输出电压范围：2.5V 至 5.5V
- 同步升压转换器效率高达 96%
- 输出电流 2.1A 的 3.3V 至 5V 电源转换
- 带有可调阈值/滞后的输入电源电压监控器
- 用于在轻载时实现高效率的省电模式
- 关断期间负载断开
- 输出过压保护
- 可编程软启动
- 电源正常输出
- 2MHz 开关频率
- 输出电容器放电 (TPS61231)
- 3mm x 3mm x 0.9mm 超薄小外形尺寸无引线 (VSON) 封装

2 应用范围

- 低压锂离子电池供电类产品
- USB 电源
- 平板电脑
- 移动电源、备用电池
- 工业仪表计量设备

3 说明

TPS6123x 器件系列是一款采用紧凑解决方案尺寸的高效同步升压转换器。它针对由单节锂离子电池或 3.3V 稳压电源轨供电的产品进行了优化。集成电路 (IC) 中集成了一个 5A 开关，并且能够在由 3.3V 输入电源供电，输出电压为 5V 时传送高达 2.1A 的输出电流。此器件基于准恒定接通时间谷值电流模式控制机制。典型运行频率为 2MHz，这样可使用小型电感器和电容器来实现小解决方案尺寸。TPS61230 和 TPS61231 通过一个外部电阻分压器提供可调输出电压，而 TPS61232 提供 5V 的固定输出电压。

轻负载期间，TPS6123x 自动进入省电模式，以最低静态电流实现最大效率。在关断期间，负载完全从输入上断开，并且输入流耗减少至 1.5 μ A (典型值)。此器件集成一个精密低功率 EN 比较器。EN 阈值以及使能比较器的滞后可由外部电阻器调节，并且支持应用专用系统加电和断电要求。还内置了其他诸如输出过压保护、热关断保护和电源正常输出等特性。

此器件采用 3mm x 3mm x 0.9mm VSON 封装。

8 Detailed Description

8.1 Overview

The TPS6123x synchronous step-up converter typically operates at a quasi-constant 2-MHz frequency pulse width modulation (PWM) at moderate to heavy load currents. At light load currents, the TPS6123x converter operates in power-save mode with pulse frequency modulation (PFM). The converter uses a novel quasi-constant on-time valley current mode control scheme which provides excellent transient line / load response with minimal output capacitance. Internal loop compensation simplifies the design process while minimizing the number of external components. The TPS6123x device can smoothly transit in and out of zero duty cycle mode (high side FET full on). Therefore the output can be kept as close as possible to its regulation limits even though the converter is subject to an input voltage that tends to be excessive.

8.2 Functional Block Diagram

(1) Output discharge block is implemented in TPS61231 only.

(2) Internal resistor divider is implemented in TPS61232 only. For adjustable output versions, the FB pin is directly connected to the negative pin of the EA.

8.3 Feature Description

8.3.1 Startup

In boost mode (PWM or PFM), the rectifying switch is turned on first until the output capacitor is charged to 0.5 V with the current limit of 550 mA after the device is enabled. Then, the output capacitor is continuously charged to a value close to the input voltage. This is called the pre-charge phase. During the pre-charge phase, the output current is limited by the pre-charge current limit of the high side rectifying switch and the SS pin voltage follows the FB voltage (in the TPS61232, the SS pin follows the internal FB voltage). Once the output capacitor has been biased to the input voltage, the device starts switching. This is called the soft start phase. During the soft

Feature Description (接下页)

start phase, the SS pin voltage limits the FB pin voltage, and the output voltage rising slope follows the SS pin voltage slope. The capacitor connected to the SS pin is charged by the internal bias current of I_{SS} , giving the time of the soft start phase shown in 公式 1. The larger the soft start capacitor, the longer the soft start phase time. Leaving the SS pin floating sets the minimum soft startup phase time. The device finishes the soft start phase and operates normally when the nominal output voltage is reached.

$$t_{SS} = \frac{C_{SS}}{5 \mu A} \times \left(1 - \frac{V_{IN}}{V_{OUT}} \right) \times V_{REF} \quad (1)$$

The SS pin voltage is discharged in the cases when the device gets disabled by the EN pin, thermal shutdown and undervoltage lockout. The SS pin may be left floating to disable the soft start phase and start up with the fastest time. In zero duty cycle mode, only the pre-charge phase works during startup.

8.3.2 Current Limit Operation

The device employs a valley current sensing scheme. Switch valley current limit detection occurs during the off time through sensing of the voltage drop across the synchronous rectifier. If the current is above the valley current limit level when it is time to turn off the synchronous rectifier, the device instead keeps the synchronous rectifier on until its current decreases below the valley current limit level. The maximum continuous output current $I_{OUT(MAX)}$, before entering switch valley current limit operation, is defined by 公式 2.

$$I_{OUT(MAX)} = (1-D) \times \left(I_{LIM_SW} + \frac{1}{2} \Delta I_L \right)$$

$$D = \frac{V_{OUT} - V_{IN}}{V_{OUT}}$$

$$\Delta I_L = \frac{V_{IN}}{L} \times \frac{D}{f_{SW}} \quad (2)$$

Where

I_{LIM_SW} = Switch valley current limit

L = Inductor value

f_{SW} = Switching frequency

When the switch current limit is reached, the output voltage decreases from further load increase. The switch valley current limit works in PWM, PFM and Zero Duty Cycle Mode operations.

Another current limit scheme, pre-charge current limit, I_{LIM_Pre} is implemented. Pre-charge current limit detection works when $V_{OUT} < V_{OUT_NOM}$ and $V_{OUT} < V_{IN}$. It can happen when the device is in the pre-charge phase or an over load condition. It impacts the minimum load resistance at startup as shown in 图 14 and 图 27.

8.3.3 Enable/Disable

The EN pin is connected to an ON/OFF detector (ON/OFF) and an input of the Enable Comparator, shown in the functional block diagram. With a voltage level of 0.4 V or less at the EN pin, the ON/OFF detector turns the device into Shutdown mode and the quiescent current is reduced to typically 1.5 μA . In this mode, the EN comparator and the entire internal control circuitry are switched off. A voltage level of typically 0.9 V at the EN pin triggers the ON/OFF detector and activates the internal reference, the EN comparator and the UVLO comparator. Once the ON/OFF detector has tripped, the quiescent current into the VIN pin is typically 1.5 μA .

The TPS6123x starts regulation once the voltage at the EN pin trips the threshold $V_{EN_TH_ON}$ and the VIN pin voltage is above the UVLO threshold. The device enters startup and ramps up the output voltage. The TPS6123x stops regulation once the voltage on the EN pin falls below the threshold $V_{EN_TH_OFF}$ or the VIN pin voltage falls below the UVLO threshold. For proper operation, The EN pin must be terminated and must not be left floating. An external logic signal applied directly to the EN pin can enable/disable the device. The device can be driven into shutdown mode by pulling the EN pin to GND. In this mode, true load disconnect between the battery and load prevents current flow from V_{IN} to V_{OUT} , as well as reverse flow from V_{OUT} to V_{IN} .

Feature Description (接下页)

8.3.4 Undervoltage Lockout

An under voltage lockout is implemented to avoid mis-operation of the device at low input voltages. It shuts down the device with voltages lower than V_{UVLO} .

Use the HYS pin to configure a new undervoltage lockout threshold and hysteresis shown in 图 10 and 公式 3. The new thresholds must be higher than V_{UVLO} ; otherwise it does not work. The device holds the HYS pin low until the EN voltage rises above $V_{EN_TH_ON}$. Then, the HYS pin goes high impedance.

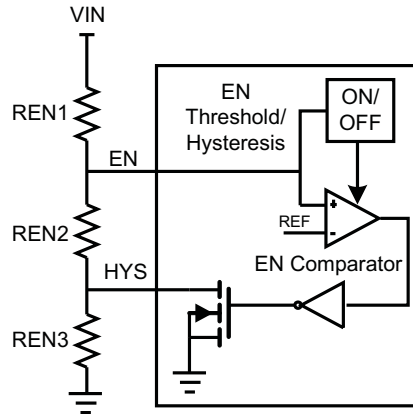

图 10. EN Comparator threshold and hysteresis setting

$$\begin{aligned}
 V_{IN_OFF} &= V_{TH_EN_OFF} \times \left(1 + \frac{REN1}{REN2 + REN3}\right) = 1.14V \times \left(1 + \frac{REN1}{REN2 + REN3}\right) \\
 V_{IN_ON} &= V_{TH_EN_ON} \times \left(1 + \frac{REN1}{REN2}\right) = 1.19V \times \left(1 + \frac{REN1}{REN2}\right)
 \end{aligned}
 \tag{3}$$

8.3.5 Output Capacitor Discharge, TPS61231

To make sure the device starts up under defined conditions, the output capacitor of the TPS61231 gets discharged by the VOUT pin with a typical discharge resistor of R_{DIS} in the cases when the device gets disabled by the EN pin, thermal shutdown, and undervoltage lockout.

8.3.6 Power Good Output

The PG output is low when the output voltage is below 90% of its nominal value. The PG pin becomes high impedance once the output is higher than 95% of its nominal voltage. The PG pin is an open drain output and is specified to sink up to 500 μA . This PG output requires a pull-up resistor that cannot be connected to any voltage higher than 5.5 V. PG is held low when the device is disabled by the EN pin and thermal shutdown.

8.3.7 Over Voltage Protection

The device stops switching as soon as the output voltage exceeds V_{OVP} . When the output voltage falls 0.15V below the OVP threshold, the device resumes normal operation until the output voltage exceeds the OVP threshold again.

8.3.8 Thermal Shutdown

The device goes into thermal shutdown and stops switching once the junction temperature exceeds T_{JSD} . Once the junction temperature falls below the threshold, it returns to normal operation automatically.

8.4 Device Functional Modes

The TPS6123x boost converter family has three operation modes, as shown in 表 1.

表 1. Operation Mode Description

MODE	DESCRIPTION	CONDITION
PWM	Boost in normal switching operation	$V_{IN} < V_{OUT} + 0.2 \text{ V}$, heavy load
PFM	Boost in power save operation	$V_{IN} < V_{OUT} + 0.2 \text{ V}$, light load
Zero Duty Cycle	Zero duty cycle operation	$V_{OUT} < V_{IN} \leq V_{OUT} + 0.24 \text{ V}$ and $V_{OUT} \geq V_{OUT_NOM}$

8.4.1 Boost Normal Mode

The TPS6123x boost converter family typically operates at a quasi-constant 2-MHz frequency pulse width modulation (PWM) at moderate to heavy load currents. Based on the V_{IN}/V_{OUT} ratio, a simple circuit predicts the required on-time. At the beginning of the switching cycle, the low-side N-MOS switch, shown in the functional block diagram, is turned on and the inductor current ramps up to a peak current that is defined by the on-time and the inductance. In the second phase, once this peak current is reached, the current comparator trips, the on-timer is reset turning off the low-side N-MOS switch and turning on the high-side rectifying switch. The current through the inductor then decays to an internally set valley current. Once this occurs, the on-timer is set to turn the boost switch back on again and the cycle is repeated.

8.4.2 Boost Power Save Mode

The device integrates a power save mode with pulse frequency modulation (PFM) to improve efficiency at light load. In power save mode, the device only switches when the output voltage trips below a set threshold voltage. It ramps up the output with several pulses and enters the power save mode when the output voltage exceeds the set threshold voltage. PFM is left and PWM mode entered when the inductor current becomes discontinuous. The DC output voltage in PFM mode rises above the nominal output voltage in PWM mode by 0.7%.

图 11. Output Voltage in PFM/PWM Mode

8.4.3 Zero Duty Cycle Mode

When the input voltage is lower than $V_{OUT} + 0.24 \text{ V}$ and V_{OUT} is higher than the nominal output voltage, the device automatically changes to a Zero Duty Cycle Mode. In Zero Duty Cycle Mode, the rectifying switch is constantly turned on and the low side switch is turned off. The output voltage in this mode depends on the resistance between the input and the output, calculated as:

$$V_{OUT} = V_{IN} - I_{OUT} \times (R_{DS(on)} + R_L) \quad (4)$$

9 Applications and Implementation

注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The devices are designed to operate from an input voltage supply range between 2.3 V and 5.5 V with a maximum output current of 2.1 A. The devices operate in PWM mode for medium to heavy load conditions and in power save mode at light load currents. In PWM mode the TPS6123x converter operates with the nominal switching frequency of 2 MHz which provides a controlled frequency variation over the input voltage range. As the load current decreases, the converter enters power save mode, reducing the switching frequency and minimizing the IC quiescent current to achieve high efficiency over the entire load current range. The WEBENCH software uses an iterative design procedure and accesses a comprehensive database of components when generating a design. See the [相关文档](#) section for additional documentation.

9.2.1.2.1 Programming the Output Voltage

The TPS6123x device family's output voltage need to be programmed via an external voltage divider to set the desired output voltage.

An external resistor divider is used, as shown in 公式 5. By selecting R1 and R2, the output voltage is programmed to the desired value. When the output voltage is regulated, the typical voltage at the FB pin is V_{FB} . The following equation can be used to calculate R1 and R2.

$$V_{OUT} = V_{FB} \times \left(1 + \frac{R1}{R2}\right) = 1V \times \left(1 + \frac{R1}{R2}\right) \quad (5)$$

For best accuracy, R2 should be kept smaller than 100 kΩ to ensure that the current following through R2 is at least 100 times larger than FB pin leakage current. Changing R2 towards a lower value increases the robustness against noise injection. Changing the R2 towards higher values reduces the quiescent current for achieving highest efficiency at low load currents.

For the fixed output voltage version, TPS61232, the FB pin must be tied to the output directly.

9.2.1.2.2 Inductor and Capacitor Selection

The second step is the selection of the inductor and capacitor components. To simplify this process, 表 4 outlines possible inductor and output capacitor value combinations.

表 4. Inductor and Output Capacitor Combinations

L (μH) ⁽¹⁾	C _{OUT} (μF) ⁽²⁾			
	10	20	47	100
0.47		√	√	√
1.0		√ ⁽³⁾	√	√
1.5				

(1) This is the nominal inductance of inductor. Inductor tolerance and current de-rating is anticipated. The effective inductance can vary by -30%.

(2) This is the effective capacitance of output capacitors. A higher nominal value is required.

(3) Typical application configuration. Other check mark indicates alternative filter combinations.

9.2.1.2.2.1 Inductor Selection

A boost converter requires two main passive components for storing energy during the conversion, an inductor and an output capacitor. It is advisable to select an inductor with a saturation current rating higher than the possible peak current flowing through the power switches. The inductor peak current varies as a function of the load, the input and output voltages and is estimated using 公式 6.

$$I_{L(PEAK)} = \frac{I_{OUT}}{(1-D) \times \eta} + \frac{1}{2} \times \frac{V_{IN} \times D}{L \times f_{SW}} \quad (6)$$

Where

η = Power conversion estimated efficiency

Selecting an inductor with insufficient saturation performance can lead to excessive peak current in the converter. This could eventually harm the device and reduce reliability. It's recommended to choose the saturation current for the inductor 20%–30% higher than the $I_{L(PEAK)}$, from 公式 6. The following inductors are recommended to be used in designs.

表 5. List of Inductors

INDUCTANCE [μH]	CURRENT RATING [A]	DC RESISTANCE [mΩ]	PART NUMBER	MANUFACTURER
1.0	5.4	10.8	XFL4020-102ME	Coilcraft
1.0	7.5	9	LQH6PPN1R0	muRata
0.47	6.6	7.6	XFL4015-471ME	Coilcraft

9.2.1.2.2.2 Output Capacitor Selection

For the output capacitor, it is recommended to use small X5R or X7R ceramic capacitors placed as close as possible to the V_{OUT} and GND pins of the IC. If, for any reason, the application requires the use of large capacitors which cannot be placed close to the IC, using a smaller ceramic capacitor of 1 μF in parallel to the large one is highly recommended. This small capacitor should be placed as close as possible to the V_{OUT} and GND pins of the IC.

Care must be taken when evaluating a capacitor's derating under bias. The bias can significantly reduce capacitance. Ceramic capacitors can lose as much as 50% of their capacitance at rated voltage. Therefore, leave margin on the voltage rating to ensure adequate effective capacitance.

The ESR impact on the output ripple must be considered as well, if tantalum or electrolytic capacitors are used. Assuming there is enough capacitance such that the ripple due to the capacitance can be ignored, the ESR needed to limit the V_{Ripple} is:

$$V_{Ripple(ESR)} = I_{L(PEAK)} \times ESR \quad (7)$$

9.2.1.2.2.3 Input Capacitor Selection

Multilayer X5R or X7R ceramic capacitors are an excellent choice for input decoupling of the step-up converter as they have extremely low ESR and are available in small footprints. Input capacitors should be located as close as possible to the device. While a 22-μF input capacitor is sufficient for most applications, larger values may be used to reduce input current ripple without limitations. Take care when using only ceramic input capacitors. When a ceramic capacitor is used at the input and the power is being supplied through long wires, such as from a wall adapter, a load step at the output can induce ringing at the VIN pin. This ringing can couple to the output and be mistaken as loop instability or could even damage the part. Additional "bulk" capacitance (electrolytic or tantalum) should in this circumstance be placed between C_{IN} and the power source to reduce ringing than can occur between the inductance of the power source leads and C_{IN}.

9.2.1.2.3 Loop Stability, Feed Forward Capacitor

The third step is to check the loop stability. The stability evaluation is to look from a steady-state perspective at the following signals:

- Switching node, SW
- Inductor current, I_L
- Output ripple, $V_{Ripple(OUT)}$

When the switching waveform shows large duty cycle jitter or the output voltage or inductor current shows oscillations, the regulation loop may be unstable. This is often a result of board layout and/or L-C combination.

The load transient response is another approach to check the loop stability. During the load transient recovery time, V_{OUT} can be monitored for settling time, overshoot or ringing that helps judge the converter's stability. Without any ringing, the loop has usually more than 45° of phase margin.

As for the heavy load transient applications such as a 2 A load step transient, a feed forward capacitor in parallel with R1 is recommended. The feed forward capacitor increases the loop bandwidth by adding a zero. This results in a lower output voltage drop, as shown in 图 36. Set the feed forward capacitor zero near 20 kHz for most applications. See application report *Optimizing Transient Response of Internally Compensated dc-dc Converters With Feedforward Capacitor* (SLVA289).

10 Power Supply Recommendations

The device is designed to operate from an input voltage supply range between 2.3 V and 5.5 V. This input supply must be well regulated. If the input supply is located more than a few inches from the converter, additional bulk capacitance may be required in addition to the ceramic bypass capacitors. An electrolytic or tantalum capacitor with a value of 47 μF is a typical choice.

11 Layout

11.1 Layout Guidelines

For all switching power supplies, the layout is an important step in the design, especially at high peak currents and high switching frequencies. If the layout is not carefully done, the regulator could show stability problems as well as EMI problems. Therefore, use wide and short traces for the main current path and for the power ground tracks. The input capacitor, output capacitor, and the inductor should be placed as close as possible to the IC. Use a common ground node for power ground and a different one for control ground to minimize the effects of ground noise. Connect these ground nodes at the GND pin of the IC. The most critical current path for all boost converters is from the switching FET, through the synchronous FET, then the output capacitors, and back to ground of the switching FET. Therefore, the output capacitors and their traces should be placed on the same board layer as the IC and as close as possible between the IC's VOUT and GND pin.

See [Figure 37](#) for the recommended layout.

11.3 Thermal Considerations

Implementation of integrated circuits in low-profile and fine-pitch surface-mount packages typically requires special attention to power dissipation. Many system-dependent issues such as thermal coupling, airflow, added heat sinks and convection surfaces, and the presence of other heat-generating components affect the power-dissipation limits of a given component.

Two basic approaches for enhancing thermal performance are listed below.

- Improving the power dissipation capability of the PCB design
- Introducing airflow in the system

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSELETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
